Please find here an excerpt of Section 4.1 from Cheng et al., 1994: "In Appendix A it is shown in detail that if the element concentration per unit area satisfies a fractal or multifractal model, then the area A(p) has indeed a power-law type relation with p. When the concentration per unit area follows a fractal model, this power-law relation has only one exponent. On the other hand, when the concentration per unit area satisfies a multifractal model with a spectrum of fractal dimensions, then several separate power-law relations between area A(p) and p can be established. For a range of p close to its minimum value $p$ the predicted multifractal power-law relations are: Equation (2a) where $C_1$ and $C$ are constants and $\alpha_1$ and $\beta_1$ are exponents associated with the maximum singularity exponent. For a range of $p$ close to its maximum value $p$, the predicted power-law relation is: Equation (2b) where $C_1$ is another constant and $C$ is the exponent associated with the minimum singularity exponent (see Appendix A)." The two extreme
asymptotical relationships are developed for p close to minimum and maximum. The appendix A contains the mathematical developments of those two asymptotical relationships, which is the heart of the article: separating geochemical "anomalies" from "background". All graphs presented in this article show one or two linear asymptotical domain in log/log space but never more than 2 linear domains. Again, several power laws can be established in the multifractal case, which apparently the case of your data but there is no rationale in the Concentration-Area model to identify them. A discussion of this point should appear in the article.
